

Homework 3

In this assignment, we'll explore some of the geometry that underlies how camera images are formed.

SUBMISSION NOTE:

1. Make sure that the first line in any Python cell with a function is the `def` line. The HW submission script will fail to detect the function unless the function definition is on the first line of the code cell in the Python Notebook.
2. Make sure the file name of the Python file you upload to Gradescope is named `hw3.py`. This is required for the autograder to run correctly.

```

1. Transformations in 3D

In order to make sense of how objects in our world are rendered in a camera, we typically need to understand how they are located relative to the camera. In this question, we'll examine some properties of the transformations that formalize this process by expressing coordinates with respect to multiple frames.

We'll be considering a scene with two frames: a world frame (W) and a camera frame (C).

Notice that:

- We have 3D points p , q , r , and s that define a square, which is parallel to the world xy plane
- C_z and C_x belong to the plane defined by W_z and W_x
- C_y is parallel to W_y

1.1 Reference Frame Definitions

First, we'll take a moment to validate your understanding of 3D reference frames.

Consider creating:

- A point w at the origin of the world frame (O_w)
- A point c at the origin of the camera frame (O_c)

Examine the x , y , and z axes of each frame, then express these points with respect to the world and camera frames. Fill in `w_wrt_camera`, `w_wrt_world`, and `c_wrt_camera`.

You can consider the length $d = 1$.

```
In [ ]: d = 1.0

# Abbreviation note:
# - "wrt" stands for "with respect to", which is ~synonymous with "relative"

w_wrt_world = np.array([0.0, 0.0, 0.0]) # Done for you
w_wrt_camera = None # Assign me below!

c_wrt_world = None # Assign me below!
c_wrt_camera = None # Assign me below!

### YOUR CODE HERE: Assign values to w_wrt_camera, w_wrt_world, and c_wrt_ca
w_wrt_camera = np.array([0.0, 0.0, d])

c_wrt_world = np.array([d/np.sqrt(2), 0.0, d/np.sqrt(2)])
c_wrt_camera = np.array([0.0, 0.0, 0.0])
### END YOUR CODE
```

```
In [9]: # Run this cell to check your answers!
assert (
    (3,)
    == w_wrt_world.shape
    == w_wrt_camera.shape
    == c_wrt_world.shape
    == c_wrt_camera.shape
), "Wrong shape!"
assert (
    hash_numpy(w_wrt_world) == "d3399b7262fb56cb9ed053d68db9291c410839c4"
), "Double check your w_wrt_world!"
assert (
    hash_numpy(w_wrt_camera) == "6248a1dcfe0c8822ba52527f68f7f98955584277"
), "Double check your w_wrt_camera!"
assert (
    hash_numpy(c_wrt_camera) == "d3399b7262fb56cb9ed053d68db9291c410839c4"
), "Double check your c_wrt_camera!"
assert (
    hash_numpy(c_wrt_world) == "a4c525cd853a072d96cade8b989a9eaf1e13ed3d"
), "Double check your c_wrt_world!"

print("Looks correct!")
```

Looks correct!

1.2 World \Rightarrow Camera Transforms

Derive the homogeneous transformation matrix needed to convert a point expressed with respect to the world frame W in the camera frame C .

Discuss the rotation and translation terms in this matrix and how you determined

them, then implement it in `camera_from_world_transform()`.

We've also supplied a set of `assert` statements below to help you check your work.

Hint #1: With rotation matrix $R \in \mathbb{R}^{3 \times 3}$ and translation vector $t \in \mathbb{R}^{3 \times 1}$, you can write transformations as 4×4 matrices:

$$\begin{bmatrix} x_C \\ y_C \\ z_C \\ 1 \end{bmatrix} = \begin{bmatrix} R & t \\ \vec{0}^\top & 1 \end{bmatrix} \begin{bmatrix} x_W \\ y_W \\ z_W \\ 1 \end{bmatrix}$$

Hint #2: Remember our 2D transformation matrix for rotations in the xy plane.

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} \cos(\theta) & -\sin(\theta) \\ \sin(\theta) & \cos(\theta) \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

To apply this to 3D rotations, you might think of this xy plane rotation as holding the z coordinate constant, since that's the axis you're rotating around, and transforming the x and y coordinates as described in the 2D formulation:

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = \begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

(Alternatively you could simply take the rotation matrix from the [Wikipedia](#) page)

Hint #3: In a homogeneous transform, the translation is applied after the rotation.

As a result, you can visualize the translation as an offset in the output frame.

The order matters! You'll end up with a different transformation if you translate and then rotate versus if you rotate first and then translate with the same offsets. In lecture 2 we discussed a formulation for a combined scaling, rotating, and translating matrix (in that order), which can be a useful starting point.

Your responses here: Write your discussion answer in this markdown cell, and implement the `camera_from_world_transform` function in the cell block below.

```
In [36]: def camera_from_world_transform(d: float = 1.0) -> np.ndarray:
          """Define a transformation matrix in homogeneous coordinates that
```

transforms coordinates from world space to camera space, according to the coordinate systems in Question 1.

Args:

`d` (float, optional): Total distance of displacement between world and origins. Will always be greater than or equal to zero. Defaults

Returns:

`T` (np.ndarray): Left-hand transformation matrix, such that $c = Tw$ for world coordinate w and camera coordinate c as column vectors
Shape = (4,4) where 4 means 3D+1 for homogeneous.

"""

`T = np.eye(4)`

YOUR CODE HERE

`theta = np.radians(45+90) #manually put in angle`

```
R = np.array([
    [np.cos(theta), 0, np.sin(theta)],
    [0, 1, 0],
    [-np.sin(theta), 0, np.cos(theta)]
])
```

`t = np.array([0,0,d]).reshape(3,1)`

`T[:3, :3] = R`

`T[:3, 3] = t.flatten()`

END YOUR CODE

`assert T.shape == (4, 4)`

`return T`

Here, we will check the outputs of your function against the reference frames from Part 1.1!

```
In [37]: # Check your answer against 1.1!
T_camera_from_world = camera_from_world_transform()

# Check c_wrt_camera against T_camera_from_world @ w_wrt_world
w_wrt_camera_computed = (T_camera_from_world @ np.append(w_wrt_world, 1.0))
print(f"w_wrt camera: expected {w_wrt_camera}, computed {w_wrt_camera_computed}")

assert np.allclose(
    w_wrt_camera, w_wrt_camera_computed
), "Error! (likely bad translation)"
print("Translation components look reasonable!")

# Check w_wrt_camera against T_camera_from_world @ c_wrt_world
c_wrt_camera_computed = (T_camera_from_world @ np.append(c_wrt_world, 1.0))
```

```
print(f"c_wrt camera: expected {c_wrt_camera}, computed {c_wrt_camera_computed}")
assert np.allclose(
    c_wrt_camera, c_wrt_camera_computed
), "Error! (likely bad rotation)"
print("Rotation components looks reasonable!")
```

w_wrt camera: expected [0. 0. 1.], computed [0. 0. 1.]

Translation components look reasonable!

c_wrt camera: expected [0. 0. 0.], computed [1.00875766e-16 0.00000000e+00 1.11022302e-16]

Rotation components looks reasonable!

1.3 Preserving Edge Orientations (Geometric Intuition)

Under the translation and rotation transformation from world coordinates to camera coordinates, which, if any, of the edges of the square retain their orientation and why?

For those that change orientation, how do they change? (e.g. translation x,y,z and rotation in one of our planes).

A sentence or two of geometric intuition is sufficient for each question, such as reasoning about the orientation of the edges and which axes we're rotating and translating about.

Your response here: Write your answer in this markdown cell.

Translation would not affect any orientation. But rotation would. However rotation is about the y axis. So edges that are parallel to the rotation axis y would retain their original orientation.

1.4 Preserving Edge Orientations (Mathematical Proof)

We'll now connect this geometric intuition to your transformation matrix. Framing transformations as matrix multiplication is useful because it allows us to rewrite the difference between two transformed points as the transformation of the difference between the original points. For example, take points a and b and a transformation matrix T : $Ta - Tb = T(a - b)$.

All of the edges in the p, q, r, s square are axis-aligned, which means each edge has a nonzero component on only one axis. Assume that the square is 1 by 1, and apply your transformation to the edge vectors $bottom = q - p$ and $left = s - p$ to show which of

these edges rotate and how.

Notation: You can apply the transformation to vectors representing the direction of each edge. If we transform all 4 corners, then the vector representing the direction of the transformed square's bottom is:

$$\begin{bmatrix} bottom'_x \\ bottom'_y \\ bottom'_z \\ 0 \end{bmatrix} = T \begin{bmatrix} q_x \\ q_y \\ q_z \\ 1 \end{bmatrix} - T \begin{bmatrix} p_x \\ p_y \\ p_z \\ 1 \end{bmatrix}$$

Using matrix rules, we can rewrite this in terms of the edges of the original square

$$\begin{bmatrix} bottom'_x \\ bottom'_y \\ bottom'_z \\ 0 \end{bmatrix} = T \begin{bmatrix} q_x - p_x \\ q_y - p_y \\ q_z - p_z \\ 0 \end{bmatrix}$$

Eliminate the $q - p$ components that you know to be 0, and then apply your transformation to obtain the vector $bottom' = q' - p'$ defined above. Do the same for $left' = s' - p'$. Which edge rotated, and which one didn't?

Your response here: Write your answer in this markdown cell.

Four edges exist:

- p-q and s-r edge

$$\begin{bmatrix} bottom'_x \\ bottom'_y \\ bottom'_z \\ 0 \end{bmatrix} = T \begin{bmatrix} q_x - p_x \\ q_y - p_y \\ q_z - p_z \\ 0 \end{bmatrix} = T \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \cos(\theta) & 0 & -\sin(\theta) & 0 \\ 0 & 1 & 0 & 0 \\ \sin(\theta) & 0 & \cos(\theta) & 1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}$$

– therefore p-q and s-r are did not rotate

- s-p and r-p edge

$$\begin{bmatrix} bottom_x' \\ bottom_y' \\ bottom_z' \\ 0 \end{bmatrix} = T \begin{bmatrix} s_x - p_x \\ s_y - p_y \\ s_z - p_z \\ 0 \end{bmatrix} = T \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \cos(\theta) & 0 & -\sin(\theta) & 0 \\ 0 & 1 & 0 & 0 \\ \sin(\theta) & 0 & \cos(\theta) & 1 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix} = \begin{bmatrix} -\sin(\theta) \\ 0 \\ \cos(\theta) \\ 0 \end{bmatrix}$$

- s-p and r-p did rotate

Interesting note: This may remind you of eigenvectors: one of these edges (the one that doesn't rotate) is an eigenvector of our transformation matrix!

1.5 Visualization

Implement `apply_transform()` to help us apply a homogeneous transformation to a batch of points.

Then, run the cell below to start visualizing our frames and the world square in PyPlot!

Using your code, we can animate a GIF that shows the transition of the square from its position in world coordinates to a new position in camera coordinates. We transform the perspective continuously from the world coordinate system to the camera coordinate system. Analogous to a homogeneous transform, you can see that we first rotate to match the orientation of the camera coordinate system, then translate to match the position of the camera origin.

If you want to see how the animation was computed or if you want to play around with its configuration, then check out `animate_transformation` in `utils.py` !

```
In [57]: def apply_transform(T: np.ndarray, points: np.ndarray) -> Tuple[np.ndarray]:
        """Apply a transformation matrix to a set of points.
```

Hint: You'll want to first convert all of the points to homogeneous coord. Each point in the (3,N) shape edges is a length 3 vector for x, y, and z. Appending a 1 after z to each point will make this homogeneous coordinate.

You shouldn't need any loops for this function.

```

Args:
    T (np.ndarray):
        Left-hand transformation matrix, such that  $c = Tw$ 
        for world coordinate  $w$  and camera coordinate  $c$  as column vectors.
        Shape = (4,4) where 4 means 3D+1 for homogeneous.
    points (np.ndarray):
        Shape = (3,N) where 3 means 3D and N is the number of points to transform.

Returns:
    points_transformed (np.ndarray):
        Transformed points.
        Shape = (3,N) where 3 means 3D and N is the number of points.
"""
N = points.shape[1]
assert points.shape == (3, N)

# You'll replace this!
points_transformed = np.zeros((3, N))

# YOUR CODE HERE

points_hom = np.append(points, np.ones([1,N]), axis = 0)
assert points_hom.shape == (4, N)

points_transformed = T @ points_hom
points_transformed = points_transformed[:3,:]
# END YOUR CODE

assert points_transformed.shape == (3, N)
return points_transformed

```

```

In [58]: from utils import (
    animate_transformation,
    configure_ax,
    plot_frame,
    plot_square,
)

# Vertices per side of the square
N = 2

# Compute vertices corresponding to each side of the square
vertices_wrt_world = np.concatenate(
    [
        np.vstack([np.zeros(N), np.linspace(1, 2, N), np.ones(N)]),
        np.vstack([np.zeros(N), np.ones(N) + 1, np.linspace(1, 2, N)]),
        np.vstack([np.zeros(N), np.linspace(2, 1, N), np.ones(N) + 1]),
        np.vstack([np.zeros(N), np.ones(N), np.linspace(1, 2, N)]),
    ],
)

```

```

        axis=1,
    )

    # Visualize our rotation!
    animate_transformation(
        "transformation.gif",
        vertices_wrt_world,
        camera_from_world_transform,
        apply_transform,
    )

    import IPython.display

    with open("transformation.gif", "rb") as file:
        display(IPython.display.Image(file.read()))

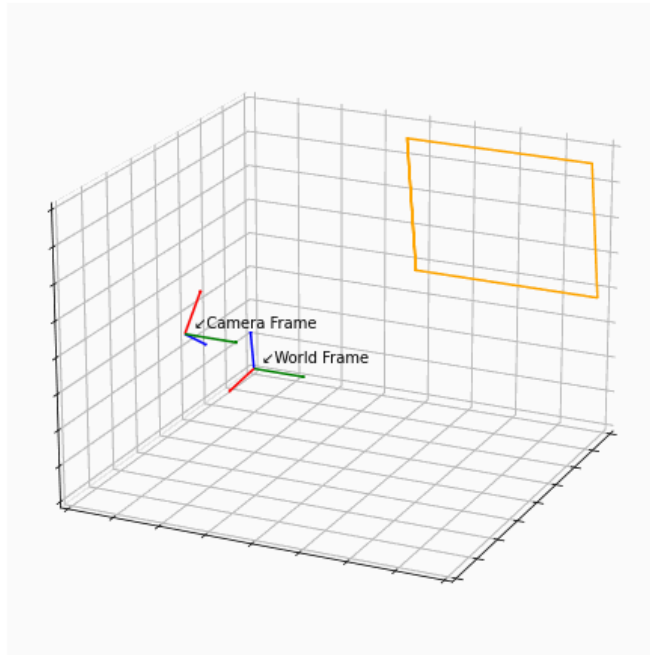

```

```

In [59]: # Compare to staff animation
with open("solution_transformation.gif", "rb") as file:
    display(IPython.display.Image(file.read()))

```

2. Camera Intrinsics & Vanishing Points

In a pinhole camera, lines that are parallel in 3D rarely remain parallel when projected to the image plane. Instead, parallel lines will meet at a **vanishing point**:

2.1 Homogeneous coordinates (5 points)

Consider a line that is parallel to a world-space direction vector in the set $\{d \in \mathbb{R}^3 : d^\top d = 1\}$. Show that the image coordinates v of the vanishing point can be written as $v = KRd$.

Hints:

- As per the lecture slides, K is the camera calibration matrix and R is the camera extrinsic rotation.
- As in the diagram above, the further a point on a 3D line is from the camera origin, the closer its projection will be to the line's 2D vanishing point.
- Given a line with direction vector d , you can write a point that's infinitely far away from the camera via a limit: $\lim_{\alpha \rightarrow \infty} \alpha d$.
- The 3D homogeneous coordinate definition is:

$$\begin{bmatrix} x & y & z & w \end{bmatrix}^\top \iff \begin{bmatrix} x/w & y/w & z/w & 1 \end{bmatrix}^\top$$

You answer here: Write your answer in this markdown cell.

World coordinates of vanishing point =

$$\lim_{\alpha \rightarrow \infty} \alpha[0, 0, d] = \lim_{\alpha \rightarrow \infty} \alpha d$$

Let $p = \alpha d$ be a point on the line for $\alpha \rightarrow \infty$. In camera coordinates, this point is

$$p_c = R(\alpha d) + t = \alpha R d + t.$$

As α becomes very large, t becomes negligible compared to $\alpha R d$, so

$$p_c \sim \alpha R d.$$

The homogeneous projection is

$$v \sim K(\alpha R d) = \alpha K R d.$$

After homogeneous normalization (ignoring the scale factor α), the vanishing point in the image is

$$v = K R d.$$

In the example given: apply rotation matrix only (no translation necessary, last term of homogeneous coordinate of vanishing point = 0 to set to infinite distance):

$$\begin{bmatrix} \cos(\theta) & 0 & -\sin(\theta) & 0 \\ 0 & 1 & 0 & 0 \\ \sin(\theta) & 0 & \cos(\theta) & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ d \\ 0 \end{bmatrix} = \begin{bmatrix} -\sin(\theta)d \\ 0 \\ \cos(\theta)d \\ 0 \end{bmatrix}$$

Apply no-skew camera intrinsic calibration matrix:

$$\begin{bmatrix} f_x & 0 & c_x & 0 \\ 0 & f_y & c_y & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} -\sin(\theta)d \\ 0 \\ \cos(\theta)d \\ 0 \end{bmatrix} = \begin{bmatrix} -f_x \sin(\theta)d + c_x \cos(\theta)d \\ c_y \cos(\theta)d \\ \cos(\theta)d \\ 0 \end{bmatrix}$$

Convert this to cartesian coordinates: \$\$

$$\begin{bmatrix} v'_x \\ v'_y \end{bmatrix}$$

=

$$\begin{bmatrix} \frac{v_x}{v_z} \\ \frac{v_y}{v_z} \end{bmatrix}$$

=

$$\begin{bmatrix} \frac{-f_x \sin(\theta)d + c_x \cos(\theta)d}{\cos(\theta)d} \\ \frac{c_y \cos(\theta)d}{\cos(\theta)d} \end{bmatrix}$$

=

$$\begin{bmatrix} -f_x \tan(\theta) + c_x \\ c_y \end{bmatrix}$$

\$\$

Because $\theta = 135$, then vector simplifies to:

$$\begin{bmatrix} f_x + c_x \\ c_y \end{bmatrix}$$

Therefore, vanishing point is a static point in the projected image, derived from KRd .

2.2 Calibration from vanishing points (5 points)

Let d_0, d_1, \dots represent directional vectors for 3D lines in a scene, and v_0, v_1, \dots represent their corresponding vanishing points.

Consider the situation when these lines are orthogonal:

$$d_i^\top d_j = 0, \text{ for each } i \neq j$$

Show that:

$$(K^{-1}v_i)^\top (K^{-1}v_j) = 0, \text{ for each } i \neq j$$

You answer here: Write your answer in this markdown cell.

From before $v = KRd$, therefore:

$$K^{-1}v = Rd$$

So then:

$$(K_i^{-1}v)^T(K_j^{-1}v) = (Rd_i)^T(Rd_j) = d_i^T R^T R d_j = d_i^T d_j = 0$$

2.3 Short Response (5 points)

Respond to the following using bullet points:

- In the section above, we eliminated the extrinsic rotation matrix R . Why might this simplify camera calibration?
- Assuming square pixels and no skew, how many vanishing points with mutually orthogonal directions do we now need to solve for our camera's focal length and optical center?
- Assuming square pixels and no skew, how many vanishing points with mutually orthogonal directions do we now need to solve for our camera's focal length when the optical center is known?

You answer here: Write your answer in this markdown cell.

- We can uncover camera intrinsics without solving for pose which reduces number of unknowns to solve for and reduces run time.
- 3, due to 3 unknowns ($f_x = f_y = f$ by square pixel condition, c_x, c_y)
- 1, due to 1 unknowns (f)

3. Intrinsic Calibration

Using the vanishing point math from above, we can solve for a camera matrix K !

First, let's load in an image. To make life easier for you, we've hand labeled a set of coordinates on it that we'll use to compute vanishing points.

```
In [60]: # Load image and annotated points; note that:
# > Our image is a PIL image type; you can convert this to NumPy with `np.as
# > Points are in (x, y) format, which corresponds to (col, row)!
img = Image.open("images/pressure_cooker.jpg")
print(f"Image is {img.width} x {img.height}")
```

```
points = np.array(
    [
        [270.0, 327.0], # [0]
        [356.0, 647.0], # [1]
        [610.0, 76.0], # [2]
        [706.0, 857.0], # [3]
        [780.0, 585.0], # [4]
        [1019.0, 226.0], # [5]
    ]
)

# Visualize image & annotated points
fig, ax = plt.subplots(figsize=(8, 10))
ax.imshow(img)
ax.scatter(points[:, 0], points[:, 1], color="white", marker="x")
for i in range(len(points)):
    ax.annotate(
        f"points[{i}]",
        points[i] + np.array([15.0, 5.0]),
        color="white",
        backgroundcolor=(0, 0, 0, 0.15),
        zorder=0.1,
    )
```

Image is 1300 x 975

3.1 Finding Vanishing Points

In 2D, notice that a vanishing point can be computed by finding the intersection of two lines that we know are parallel in 3D.

To find the vanishing points in the image, implement `intersection_from_lines()`.

Then, run the cell below to check that it's working.

Note that later parts of this homework will fail if you choose the side face instead of the front face for producing the leftmost vanishing point.

```
In [85]: def intersection_from_lines(
          a_0: np.ndarray, a_1: np.ndarray, b_0: np.ndarray, b_1: np.ndarray
        ) -> np.ndarray:
          """Find the intersection of two lines (infinite length), each defined by
             pair of points.

             Args:
```

```

a_0 (np.ndarray): First point of first line; shape `(2,)`.
a_1 (np.ndarray): Second point of first line; shape `(2,)`.
b_0 (np.ndarray): First point of second line; shape `(2,)`.
b_1 (np.ndarray): Second point of second line; shape `(2,)`.

Returns:
    np.ndarray:
    """
    # Validate inputs
    assert a_0.shape == a_1.shape == b_0.shape == b_1.shape == (2,)
    assert a_0.dtype == a_1.dtype == b_0.dtype == b_1.dtype == float

    # Intersection point between lines
    out = np.zeros(2)

    # YOUR CODE HERE
    a_0 = np.append(a_0, 1) #convert to homogenous
    a_1 = np.append(a_1, 1)
    b_0 = np.append(b_0, 1)
    b_1 = np.append(b_1, 1)

    d_a = np.cross(a_0, a_1) #obtain lines
    d_b = np.cross(b_0, b_1)

    # Convert back to Cartesian by dividing by w
    out = np.cross(d_a, d_b)[:2] / np.cross(d_a, d_b)[2]
    # END YOUR CODE

    assert out.shape == (2,)
    assert out.dtype == float

    return out

```

```

In [86]: # Python trivia: the following two assert statements are the same.
# > https://docs.python.org/3/tutorial/controlflow.html#unpacking-argument-list
# > https://numpy.org/doc/stable/reference/arrays.indexing.html#integer-arrays
assert np.allclose(
    intersection_from_lines(points[0], points[1], points[4], points[0],),
    points[0],
)
assert np.allclose(intersection_from_lines(*points[[0, 1, 4, 0]]), points[0])
print("Looks correct!")

```

Looks correct!

To use the constraint we derived above, we need to find vanishing points that correspond to three orthogonal direction vectors.

Populate `v0_indices`, `v1_indices`, and `v2_indices`, then run the cell below to

compute `v`.

You should be able to get an output that looks like this (color ordering does not matter):

```
In [87]: # Select points used to compute each vanishing point
#
# Each `v*_indices` list should contain four integers, corresponding to
# indices into the `points` array; the first two ints define one line and
# the second two define another line.
v0_indices = None
v1_indices = None
v2_indices = None

### YOUR CODE HERE: Instantiate v*_indices!
v0_indices = [2, 5, 0, 4]
v1_indices = [2, 0, 5, 4]
v2_indices = [0, 1, 4, 3]
### END YOUR CODE

# Validate indices
assert (

3.2 Computing Optical Centers

Next, implement `optical_center_from_vanishing_points()` to compute the 2D optical center from our vanishing points. Then, run the cell below to compute a set of optical center coordinates from our vanishing points.

Hint: Property 3 from [1] may be useful. (Try connecting to Stanford campus network otherwise the paper link might not work for you.)

[1] Caprile, B., Torre, V. **Using vanishing points for camera calibration.**
Int J Comput Vision 4, 127–139 (1990). <https://doi.org/10.1007/BF00127813>

```
In [ ]: def optical_center_from_vanishing_points(
    v0: np.ndarray, v1: np.ndarray, v2: np.ndarray
) -> np.ndarray:
    """Compute the optical center of our camera intrinsics from three vanish
    points corresponding to mutually orthogonal directions.

    Hints:
    - Your `intersection_from_lines()` implementation might be helpful here.
    - It might be worth reviewing vector projection with dot products.

    Args:
        v0 (np.ndarray): Vanishing point in image space; shape `(2,)`.
        v1 (np.ndarray): Vanishing point in image space; shape `(2,)`.
        v2 (np.ndarray): Vanishing point in image space; shape `(2,)`.

    Returns:
        np.ndarray: Optical center; shape `(2,)`.

3.3 Computing Focal Lengths

Consider two vanishing points corresponding to orthogonal directions, and the constraint from above:

$$(K^{-1}v_0)^\top (K^{-1}v_1) = 0, \text{ for each } i \neq j$$

Derive an expression for computing the focal length when the optical center is known, then implement `focal_length_from_two_vanishing_points()`.

When we assume square pixels and no skew, recall that the intrinsic matrix K is:

$$K = \begin{bmatrix} f & 0 & c_x \\ 0 & f & c_y \\ 0 & 0 & 1 \end{bmatrix}$$

Hint: Optional, but this problem maybe be simpler if you factorize K as:

$$K = \begin{bmatrix} 1 & 0 & c_x \\ 0 & 1 & c_y \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

When working with homogeneous coordinates, note that the lefthand matrix is a simple translation.

```
In [127... def focal_length_from_two_vanishing_points(
    v0: np.ndarray, v1: np.ndarray, optical_center: np.ndarray
) -> np.ndarray:
    """Compute focal length of camera, from two vanishing points and the
    calibrated optical center.

    Args:
        v0 (np.ndarray): Vanishing point in image space; shape `(2,)`.
        v1 (np.ndarray): Vanishing point in image space; shape `(2,)`.
        optical_center (np.ndarray): Calibrated optical center; shape `(2,)`.

    Returns:
        float: Calibrated focal length.
    """
    assert v0.shape == v1.shape == optical_center.shape == (2,), "Wrong shape"

    f = None

    # YOUR CODE HERE
    x0, y0 = v0
    x1, y1 = v1
    cx, cy = optical_center
    f = np.sqrt(-((x0 - cx) * (x1 - cx) + (y0 - cy) * (y1 - cy)))

    # END YOUR CODE

    return float(f)
```

```
In [128... # If your implementation is correct, these should all be ~the same
f = focal_length_from_two_vanishing_points(v[0], v[1], optical_center)
print(f"Focal length from v0, v1: {f}")

print(f"Focal length from v0, v2: {f}")
```

```
Focal length from v0, v1: 1056.992519708474
Focal length from v1, v2: 1056.992519708474
Focal length from v0, v2: 1056.9925197084738
```

3.4 Comparison to EXIF data

To validate our focal length computation, one smoke test we can run is compare it to parameters supplied by the camera manufacturer.

In JPEG images, these parameters and other metadata are sometimes stored using [EXIF](#) tags that are written when the photo is taken. Run the cell below to read & print some of this using the Python Imaging Library!

```
In [129... from PIL.ExifTags import TAGS

# Grab EXIF data
exif = {TAGS[key]: value for key, value in img._getexif().items()}

# Print subset of keys
print(f"EXIF data for {img.filename}\n=====")
for key in (
    "DateTimeOriginal",
    "FocalLength",
    "GPSInfo",
    "Make",
    "Model",
):
    print(key.ljust(25), exif[key])
```

```
EXIF data for /Users/jasonsun/Desktop/CS131/CS131_release/winter_2025/hw3_release/images/pressure_cooker.jpg
=====
```

```
DateTimeOriginal      2020:11:06 01:02:20
FocalLength           4.3
GPSInfo               {1: 'N', 2: (37.0, 25.0, 29.903), 3: 'W', 4: (122.0, 9.0, 34.294), 5: b'\x00', 6: 0.0}
Make                  samsung
Model                 SM-G970U
```

From above, we see that the focal length of our camera system is **4.3mm**.

Focal lengths are typically in millimeters, but all of the coordinates we've worked with thus far have been in pixel-space. Thus, we first need to convert our focal length from pixels to millimeters.

Try to visualize this conversion, then implement

physical_focal_length_from_calibration().

```
In [132... def physical_focal_length_from_calibration(
    f: float, sensor_diagonal_mm: float, image_diagonal_pixels: float
) -> float:
```

```

"""Compute the physical focal length of our camera, in millimeters.

Args:
    f (float): Calibrated focal length, using pixel units.
    sensor_diagonal_mm (float): Length across the diagonal of our camera
        sensor, in millimeters.
    image_diagonal_pixels (float): Length across the diagonal of the
        calibration image, in pixels.

Returns:
    float: Calibrated focal length, in millimeters.
"""
f_mm = None

# YOUR CODE HERE
image_width_pixels = image_diagonal_pixels / np.sqrt(2)
sensor_width_mm = sensor_diagonal_mm / np.sqrt(2)

f_mm = f * sensor_width_mm / image_width_pixels

# END YOUR CODE

return f_mm

```

```

In [133]: # Length across sensor diagonal for SM-G970U (Galaxy S10e)
# > https://en.wikipedia.org/wiki/Samsung_CMOS
sensor_diagonal_mm = 7.06

# Length across image diagonal
image_diagonal_pixels = np.sqrt(img.width ** 2 + img.height ** 2)

f_mm = physical_focal_length_from_calibration(
    f, sensor_diagonal_mm, image_diagonal_pixels,
)
print(f"Computed focal length:".ljust(30), f_mm)

error = np.abs(f_mm - 4.3) / 4.3
print("Calibration vs spec error:".ljust(30), f"{error * 100:.2f}%")
assert 0.06 < error < 0.07

```

```

Computed focal length:      4.592225962548816
Calibration vs spec error:  6.80%

```

3.5 Analysis (5 points)

If everything went smoothly, your computed focal length should only deviate from the manufacturer spec by ~6.8%.

Aside from manufacturing tolerances, name two or more other possible causes for

this error, then discuss the limitations of this calibration method.

You answer here: Write your answer in this markdown cell.

1. Due to parallax, if the vanishing point was off by a few pixels due to edge detection being inaccurate, you can have movements in the focal length that scales up as the features are further away from the vanishing point.
2. There might be lens distortion that were not accounted for.

The calibration method relies on the prediction of the vanishing points to be accurate to their locations in a true pinhole camera. So if either the accuracy changes, or the location of the actual vanishing point deviates due to camera intrinsics being not accurately modeled by K , the calibration will be off.

4 Extra Credit

You can choose to attempt both, either, or neither! This will be factored towards your final grade.

a) Projection

Generate a set of geometric shapes: cylinders, cubes, spheres, etc. Then, use your calibrated intrinsics to render them into the scene (i.e. overlaying them onto the image from Q3) with correct perspective.

These can be simple wireframe representations (eg `plt.plot()`); no need for fancy graphics.

b) Extrinsic Calibration *(Hard, possibly requires a lot of Google)*

Given that our box is 340mm (L) x 310mm (W) x 320mm (H), compute a 3D transformation (position, orientation) between the center of the box and the camera. In your submission, describe your approach and verify it by using both your calibrated extrinsics and intrinsics to overlay the image with a wireframe version of the box.
